Analysis Report

Global dataset report

This report is the output of the Amazon SageMaker Clarify analysis. The report is split into following parts:

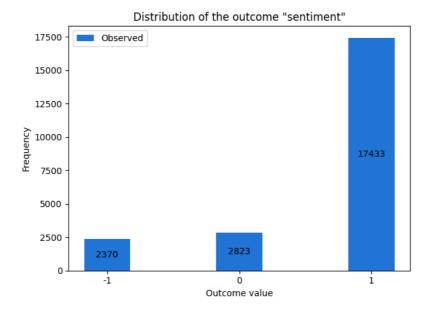

- 1. Analysis configuration
- 2. Pretraining bias metrics

Analysis Configuration

Bias analysis requires you to configure the outcome label column, the facet and optionally a group variable. Generating explanations requires you to configure the outcome label. You configured the analysis with the following variables. The complete analysis configuration is appended at the end.

Outcome label: You chose the column sentiment in the input data as the outcome label. Bias metric computation requires designating the positive outcome. You chose sentiment = 1 as the positive outcome. sentiment consisted of values [-1, 0, 1].

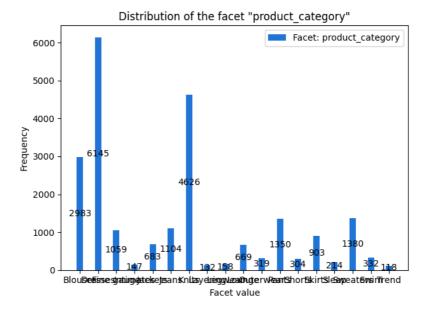

The figure below shows the distribution of values of sentiment .

Facet: You chose the column product_category in the input data as the facet. product_category consisted of values ['Blouses', 'Dresses', 'Fine gauge', 'Intimates', 'Jackets', 'Jeans', 'Knits', 'Layering', 'Legwear', 'Lounge', 'Outerwear', 'Pants', 'Shorts', 'Skirts', 'Sleep', 'Sweaters', 'Swim', 'Trend'] . Bias metrics were computed by comparing the inputs product_category = Blouses with all other inputs, then by comparing inputs product_category = Dresses with all other inputs, then by comparing inputs product_category = Rnits with all other inputs, then by comparing inputs product_category = Intimates with all other inputs, then by comparing inputs product_category = Outerwear with all other inputs, then by comparing inputs product_category = Sweaters with all other inputs, then by comparing inputs product_category = Skirts with all other inputs, then by comparing inputs product_category = Fine gauge with all other inputs, then by comparing inputs product_category = Sleep with all other inputs, then by comparing inputs product_category = Swim with all other inputs, then by comparing inputs product_category = Swim with all other inputs, then by comparing inputs product_category = Trend with all other inputs, then by comparing inputs product_category = Legwear with all other inputs, then by comparing inputs product_category = Deans with all other inputs, then by comparing inputs product_category = Deans with all other inputs, then by comparing inputs product_category = Deans with all other inputs, then by comparing inputs product_category = Deans with all other inputs, then by comparing inputs product_category = Deans with all other inputs, then by comparing inputs product_category = Deans with all other inputs, then by comparing inputs product_category = Deans with all other inputs, then by comparing inputs product_category = Deans with all other inputs, then by comparing inputs product_category = Deans with all other inputs, then by comparing inputs product_category = Deans with all other inputs, then by comp

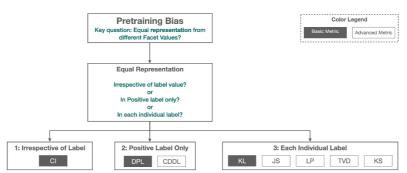

Shorts with all other inputs, then by comparing inputs product category = Layering with all other inputs.

The figure below shows the distribution of values of product category.

Pre-training Bias Metrics

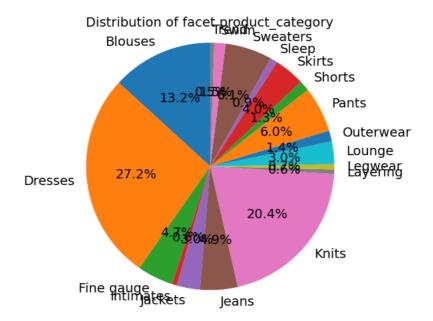

Pretraining bias metrics measure imbalances in facet value representation in the training data. Imbalances can be measured across different dimensions. For instance, you could focus imbalances within the inputs with positive observed label only. The figure below shows how different pretraining bias metrics focus on different dimensions. For a detailed description of these dimensions, see <u>Learn How Amazon SageMaker Clarify Helps Detect Bias</u>.

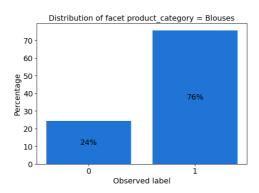

The metric values along with an informal description of what they mean are shown below. For mathematical formulas and examples, see the <u>Measure Pretraining Bias</u> section of the AWS documentation.

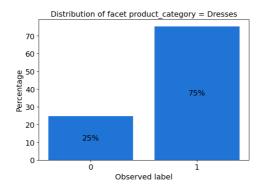

We computed the bias metrics for the label sentiment using label value(s)/threshold sentiment = 1 for the following facets:

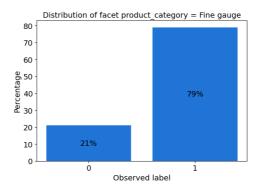

• Facet column: **product_category**The pie chart shows the distribution of facet column product_category in your data.

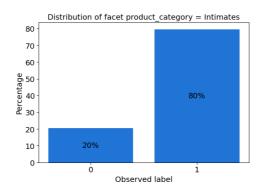

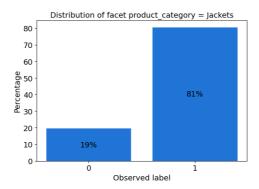

The bar plot(s) below show the distribution of facet column product_category in your data.

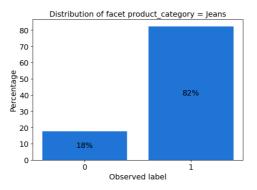

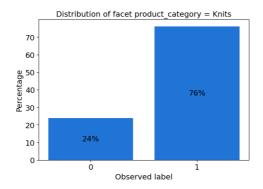

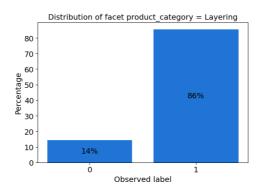

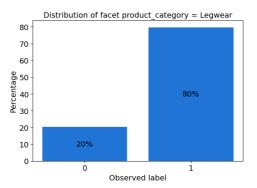

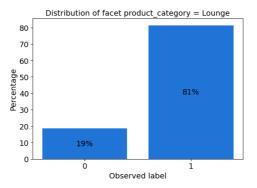

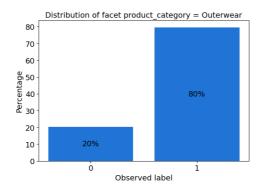

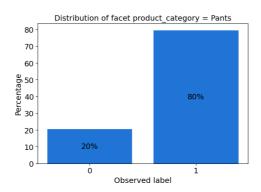

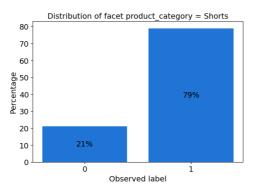

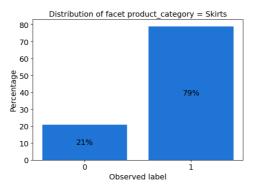

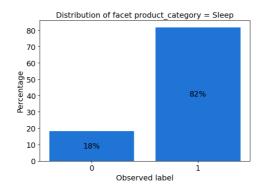

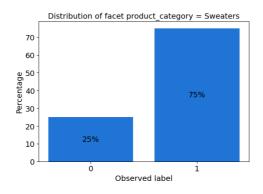

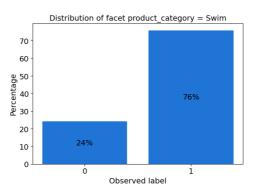

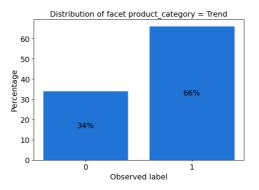

Facet Value(s)/Threshold: product_category = Blouses

Metric	Description	Value
Class Imbalance (CI)	Measures the imbalance in the number of inputs with facet values Sex=0 and rest of the inputs.	0.736
<u>Difference in</u> <u>Proportions of Labels</u> (DPL)	Measures the imbalance of positive observed labels between facet values Sex=0 and rest of the inputs.	0.016
<u>Jensen-Shannon</u> <u>Divergence (JS)</u>	Measures how much the observed label distributions of facet values Sex=0 and rest of the inputs diverge from each other entropically.	0.000
<u>Kullback-Leibler</u> <u>Divergence (KL)</u>	Measures how much the observed label distributions of facet values Sex=0 and rest of the inputs diverge from each other entropically.	0.001
Kolmogorov-Smirnov (KS)	Measures maximum divergence between the observed label distributions for facet values $Sex=0$ and rest of the inputs in the dataset.	0.016
<u>Lp-norm (LP)</u>	Measures a p-norm difference between the observed label distributions associated with facet values $Sex=0$ rest of the inputs in the dataset.	0.023
Total Variation Distance (TVD)	Measures half of the L1-norm difference between the observed label distributions associated with facet values $Sex=0$ and rest of the inputs in the dataset.	0.016

Facet Value(s)/Threshold: product_category = Dresses

	Description	Value
Class Imbalance (CI)	Measures the imbalance in the number of inputs with facet values Sex=0 and rest of the inputs.	0.457

(TVD) acet Value(s)/Thresho Metric Class Imbalance (CI) Difference in Proportions of Labels (DPL) Jensen-Shannon Divergence (JS) Kullback-Leibler Divergence (KL) Kolmogorov-Smirnov	with facet values Sex=0 and rest of the inputs in the dataset. Did: product_category = Layering Description Measures the imbalance in the number of inputs with facet values Sex=0 and rest of the inputs. Measures the imbalance of positive observed labels between facet values Sex=0 and rest of the inputs. Measures how much the observed label distributions of facet values Sex=0 and rest of the inputs diverge from each other entropically. Measures how much the observed label distributions of facet values Sex=0 and rest of the inputs diverge from each other entropically. Measures maximum divergence between the observed label distributions for facet values	Value 0.988 -0.086 0.006
